### NEW QUESTION: 3

- B. beacons received on point-to-point links

Link state protocols, sometimes called shortest path first or distributed database protocols, are built around a well-known algorithm from graph theory, E. W. Dijkstra's shortest path algorithm. Examples of link state routing protocols are:

Open Shortest Path First (OSPF) for IP

The ISO's Intermediate System to Intermediate System (IS-IS) for CLNS and IP

DEC's DNA Phase V

Novell's NetWare Link Services Protocol (NLSP)

Although link state protocols are rightly considered more complex than distance vector protocols, the basic functionality is not complex at all:

- 1 . Each router establishes a relationship-an adjacency-with each of its neighbors.
- 2 . Each router sends link state advertisements (LSAs), some
- 3 . Each router stores a copy of all the LSAs it has seen in a database. If all works well, the databases in all routers should be identical.
- 4 . The completed topological database, also called the link state database, describes a graph of the internetwork. Using the Dijkstra algorithm, each router calculates the shortest path to each network and enters this information into the route table.
