NEW QUESTION: 2

Where are Leap Availability Zones configured?

- A. Prism Central
- B. Prism Element
- C. Cloud Connect
- D. Controller VM

Answer: A

Explanation:

Terminology

* Availability Zone - it is represented by all resources (Nutanix Clusters) connected to Prism Central or Xi Leap Availability zone. Depends on the architecture, Availability zone can represent geographic territory, datacenter or server room in the datacenter. Protection policies - in protection policies you set up (RPO, Retention), rules to auto-apply policies to virtual machines

NEW QUESTION: 3

Which of the following BEST describes a block cipher?

- A. An asymmetric key algorithm that operates on a variable-length block of plaintext and transforms it into a fixed-length block of ciphertext
- B. A symmetric key algorithm that operates on a fixed-length block of plaintext and transforms it into a fixed-length block of ciphertext
- C. A symmetric key algorithm that operates on a variable-length block of plaintext and transforms it into a fixed-length block of ciphertext
- D. An asymmetric key algorithm that operates on a fixed-length block of plaintext and transforms it into a fixed-length block of ciphertext

Answer: B

Explanation:

A block cipher breaks the plaintext into fixed-length blocks, commonly 64-bits, and encrypts the blocks into fixed-length blocks of ciphertext. Another characteristic of the block cipher is that, if the same key is used, a particular plaintext block will be transformed into the same ciphertext block. Examples of block ciphers are DES, Skipjack, IDEA, RC5 and AES. An example of a block cipher in a symmetric key cryptosystem is the Electronic Code Book (ECB) mode of operation. In the ECB mode, a plaintext block is transformed into a ciphertext block as shown in Figure. If the same key is used for each transformation, then a Code Book can be compiled for each plaintext block and corresponding ciphertext block.

Answer a is incorrect since it refers to a variable-length block of plaintext being transformed into a fixed-length block of ciphertext.

Recall that this operation has some similarity to a hash function, which takes a message of arbitrary length and converts it into a fixedlength message digest.

* Answers "An asymmetric key algorithm that operates on a variable-length block of plaintext and transforms it into a fixed-length block of ciphertext" and "An asymmetric key algorithm that operates on a fixed-length block of plaintext and transforms it into a fixed-length block of ciphertext" are incorrect because they involve asymmetric key algorithms, and the block cipher is used with symmetric key algorithms.

In other cryptographic modes of operation, such as Cipher Block Chaining (CBC), the result of the encryption of the plaintext block, P_n, is fed into the encryption process of plaintext block P_{n+1}. Thus, the result of the encryption of one block affects the result of the encryption of the next block in the sequence.
